REMARKS

In view of the forgoing preliminary amendment to the claims, it is submitted that all of the claims remaining in the application are now in condition for allowance and such action is respectfully requested. Should any questions arise in connection with this application or should the Examiner believe that a telephone conference with the undersigned would be helpful in resolving any remaining issues pertaining to this application, the undersigned respectfully requests that she be contacted at the number indicated below.

For the reasons outlined above, withdrawal of the rejection of record and an allowance of this application are respectfully requested.

Respectfully submitted,

By:

(Substitute Specification With Markings) ASYNCHRONOUS MESSAGING IN STORAGE AREA NETWORK 5 Field of the Invention **BACKGROUND OF THE INVENTION Technical Field** -This invention relates to systems for asynchronous messaging-and-10 queuing, and more particularly for the control of storage of messages. Background of the Invention **Description Of The Prior Art** 15 ———Asynchronous messaging-and-queuing systems are well known in the art. One such is the IBM MQSeries MQSeries messaging-and-queuing product. (IBM and MQSeries are registered trade marks of IBM Corporation.) An MQSeries system is used in the following description, for convenience, but it will be clear to one skilled in the art that the background to the present invention comprises many other messaging-and-20 queuing systems. In an MQSeries message queuing system, a system program known as a "queuemanager" provides message queuing services to a group of applications which use the queue manager to send and receive messages over a network. A number of queue 25 managers may be provided in the network, each servicing one or more applications local to that queue manager. A message sent from one application to another is stored in a message queue maintained by the queue manager local to the receiving application until until the receiving application is ready to retrieve it. Applications can retrieve messages from queues maintained by their local queue manager, and can, via the 30 intermediary of their local queue manager, put messages on queues maintained by queue

managers throughout the network. An application communicates with its local queue manager via an interface known as the MQI (Message Queue Interface). This defines a set of requests, or "calls", that an application uses to invoke the services of the queue manager. In accordance with the MQI, an application first requests the resources which will be required for performance of a service, and, having received those resources from the queue manager, the application then requests performance of the service specifying the resources to be used. In particular, to invoke any queue manager service, an application first requires a connection to the queue manager. Thus the application first issues a call requesting a connection with the queue manager, and, in response to this call, the queue manager returns a connection handle identifying the connection to be used by the application. The application will then pass this connection handle as an input parameter when making other calls for the duration of the connection. The application also requires an object handle for each object, such as a queue, to be used in performance of the required service. Thus, the application will submit one or more calls requesting object handles for each object to be used, and appropriate object handles will be dispensed by the queue manager. All object handles supplied by the queue manager are associated with a particular connection handle, a given object handle being supplied for use by a particular connection, and hence for use together with the associated connection handle. After receiving the resources to be used, the application can issue a service request call requesting performance of a service. This call will include the connection handle and the object handle for each object to be used. In the case of retrieving a message from a queue for example, the application issues a "get message" call including its connection handle and the appropriate queue handle dispensed to the application to identify the connection and queue to the queue manager.

GB920020038GB1 5GB9-2002-0038-US1

	In a second aspect, the present invention provides a method for controlling
	a computer system having In a further aspect of the invention, an asynchronous
	messaging and queuing system and message-and-queue system is provided with a storage
	area network having astorage area network controller; comprising the steps of: receiving a
5	message request at a queue manager; and passing said message request to said storage
	area network controller; wherein said controller to manage a queue in the storage area
	network. The storage area network controller comprises control means to control
	message queues on behalf of one or more queue managers. includes means to control a
	transactional or persistent message.
10	
	Preferred method features of the method of the second aspect correspond to the means provided by preferred features of the first aspect.
15	In a third aspect, the present invention provides a computer program to cause a computer system perform computer program steps corresponding to the steps of the method of the second aspect.
20	Using a Storage Area Network (SAN) to hold the message data not only centralizes data storage, it also provides a more robust overall solution, as there is no single point of failure.
	In an even further aspect of the invention, a method is provided for controlling
	messaging. A queue in a storage area network of an asynchronous messaging and
	queuing system is managed, and a transactional or persistent message is controlled.

20

In yet a further aspect of the invention, an article is provided in a computer-readable signal-bearing medium. Means in the medium are provided for managing a queue in a storage area network of an asynchronous messaging and queuing system. In addition, means in the medium are provided for controlling a transactional or persistent message in the queue.

Other features and advantages of this invention will become apparent from the following detailed description of the presently preferred embodiment of the invention, taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a block diagram representing the component parts of a system according to a preferred embodiment of the present invention, and is suggested for printing on the first page of the issued patent.

Figure 2 is illustrative of the load-balancing capability of a system according to a preferred embodiment of the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Overview One definition of SAN is a high-speed A storage area network (SAN) is used to centralize and control message data and to eliminate a single point of failure in the message system. The SAN is a high speed network, comparable to a LAN, that allows the establishment of direct connections between storage devices and processors (servers) processors. The SAN can be viewed as an extension to the storage bus concept that enables storage devices and servers to be interconnected using similar elements as in

	Local Area Networks (LANs) and Wide Area Networks (WANs): routers, hubs, switches
	and gateways. local area networks and wide area networks. A SAN can be shared between servers and/or dedicated to one server. It can be local or can be extended over geographical distances.
5	distances. With implementation
10	It would be possible, in an embodiment of the present invention, to merely agree a set of protocols for data integrity, transactionality, and other qualities of service between the various cooperating components. In such a case, data integrity, syncpoint coordination, etc. would be conducted and controlled by a middleware layer, which would supply the appropriate set of primitives to the SAN controller and to the applications and queue managers.
	apprications and queue managers.
15	By contrast, not only does the presently most preferred embodiment of this invention remove theof the SAN, storage of messages are removed from individual servers and instead store themstored at the networklevel, in a SAN, but also provides the
	support infrastructure in the SAN to supply all required data integrity functionality, allowing multiple queue managers to access the queue (for read and write operations)simultaneously, with complete confidence.
20	Conventionally, a queue is owned by a specific queue manager, which is responsible for ensuring that multi-threaded access to that queue is maintained in an orderly and correct manner. By moving the queue to the SAN,level. The queue is also moved to the SAN and ownership of the queue is removed from the queue manager and is vested with thea SAN controller. Queue managers can apparently access and manipulate
25	messages on the queue as they would a locally owned queue, but the real, underlying management of the manipulation is maintained within the SAN controller.
	In order for this to work, the SAN Controller may provide the primitives
	required to control the controller which provides primitives to control locking and
30	transactional integrity for the messages on the queue(s) it owns.
35	There are several benefits in the preferred embodiments of the present invention. The first is that messages (data) are removed from the more fragile application server environment into the more robust SAN, where, instead of only being accessible by one server, potentially any server which can connect to the SAN can access the messages.
	The same benefits cannot be gained simply by mounting the file system holding the queue data, where multiple servers could potentially mount and use the files. If this
40	were to be allowed, conflict situations where, for example, messages locked by one queue manager were deleted by another would rapidly arise, and would make any such system 7

completely unworkable. By adding locking and two phase commit primitives to the SAN Controller, a preferred embodiment of the present invention allows multiple servers to connect to the 5 SAN and thus simultaneously access the messages on queues (for reads, writes, deletes, locks and transactional operations), with the same level of data integrity that is offered by a single queue manager controlling multi-threaded access to a single queue. A secondary benefit is that it is possible to filter all messages inbound to a 10 particular application to one queue maintained in the SAN. From there they can be distributed to any number of connected servers for subsequent processing by the application with complete transparency to the application. The final main benefit is that since all message data is centrally located, providing 15 for backup and disaster recovery is greatly simplified, as all pertinent data is located in one place, and base SAN services can be utilized to ensure that a secure copy is made. Messages can have the property of being "persistent"—that is they must be logged and journaled by the queue manager before any subsequent processing can occur or they 20 can be "non-persistent", in which case the message is discarded in the event of a queue manager failure. Preferred embodiments of the present invention are particularly suitable for the control of queues where persistent messages may be placed. The requirement for securing data is the same in a queue controlled by the SAN as 25 it is in a queue locally controlled by a queue manager - that is, authority is required to create and delete a queue, as well as to write and read messages to and from the queue. There are already mechanisms in place (queue clustering) for publishing queue definitions to multiple queue managers, and for providing access control (the local queue manager would determine if access was valid). 30 The SAN Controller would preferably police the connection of queue managers to the SAN, and thereafter assume that a request for queue manipulation sent by a connected queue manager had been validated. 35 Since message data would be flowing over networks, the option to encrypt the data between the SAN and the queue manager would also be a preferred feature. It will be clear to one skilled in the art that the presently preferred embodiment involves the transfer of attributes and activities normally associated with a middleware 40 layer distributed about a networked system into a SAN controller in order to achieve improved robustness, scalability, centralisation of control and ease of maintenance, among other advantages. The attributes and activities associated with middleware are

often referred to as "Quality of Service" definitions. It would be possible, as described above, simply to transfer the queue data structures from the local storage of the queue managers into the SAN, and leave the queue managers to negotiate protocols among themselves to manage locking and syncpointing, possibly by means of the conventional 5 middleware provisions. However, as described above, the presently most preferred embodiment of the present invention offers advantages that go beyond those offered by such a solution. As will be clear to one skilled in the art, there will be many other "Quality of 10 Service" definitions that can be incorporated into a SAN controller in the same way as can transactionality, syncpoint coordination, recoverability and so on. One example of such a Quality of Service definition is "Compensability" for subtransactions of a longrunning transaction. 15 BRIEF DESCRIPTION OF THE DRAWINGS A preferred embodiment of the present invention will now be described by way of example only, with reference to the accompanying drawings, in which: Figure 1 is a block diagram representing the component parts of a system according to a 20 preferred embodiment of the present invention; and Figure 2 is illustrative of the load balancing capability of a system according to a preferred embodiment of the present invention. 25 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT **Technical Details** -Turning now to Figure 1, there are three main components of presently 30 preferred embodiments of this invention which interact. The first is the SAN (102). controlled by the SAN controller (104); the (104). The second is the queue manager (114), which is writing the message to a queue (108) held in the SAN and the SAN. The third is a queue manager (122), looking to read that message from the SAN held queue (108). Each queue manager (114, 122) is acting on behalf of an application (112, 120) 35 that is making requests that must be satisfied by the queue manager (114, 122). The queue managers (114, 122) and the requesting applications (112, 120) may be located

anywhere in a network. That is, systems or system components (110, 118) can be regions or partitions within a system, separate physical computer systems, distributed systems in a network, or any other combination of systems or system components.

5

10

15

20

-In particular, to invoke any queue manager service, an application (112, 120) first requires a connection to the queue manager (114, 122). Thus the application (112, 120) first issues a call requesting a connection with the queue manager (114, 122), and, in response to this call, the queue manager returns a connection handle identifying the connection to be used by the application. The application (112, 120) will then pass this connection handle as an input parameter when making other calls for the duration of the connection. The application (112, 120) also requires an object handle for each object. such as a queue (108), to be used in performance of the required service. Thus, the application (112, 120) will submit one or more calls requesting object handles for each object to be used, and appropriate object handles will be dispensed by the queue manager (114, 122).122). All object handles supplied by the queue manager (114, 122) are associated with a particular connection handle, a given object handle being supplied for use by a particular connection, and hence for use together with the associated connection handle. After receiving the resources to be used, the application (112, 120) can issue a service request call requesting performance of a service. This call will include the connection handle and the object handle for each object to be used. In the case of retrieving a message from a queue (108), for example, the application issues a "get message" call including its connection handle and the appropriate queue handle dispensed to the application to identify the connection and queue (108) to the queue manager (114,

25

122).

Preferably, the SAN controller (104) of the preferred embodiment of the present invention is provided with a syncpoint coordinator (124), a persistence manager (126) and a lock manager (128). This enables centralization of functions that would

otherwise be devolved out to the queue managers, leading to potential problems that may arise in conventional messaging-and-queuing systems.

The preferred embodiment of the present invention is a highly suitable architecture for high throughput systems, with no chance of messages becoming "trapped" in a failed server, and the application throughput can also be "scaled up" by simply connecting more servers to the SAN. Conversely, if demand for the application falls, servers can be disconnected and the maximum possible throughput reduced, on a dynamic basis. As shown in Figure 2, if demand for processing messages in queue

<u>queue</u> (208) rises beyond the capacity of one or more application servers (210), one or more expansion servers (212) can be connected to the SAN, and thus added to the available processing resource available.

Below are described the interactions that may be provided in a presently preferred embodiment of the invention.

Interaction 1 - Connection

100 Queue 100 Queue Manager sends connection request to SAN Controller
 105 SAN 105 SAN Controller accepts connection request
 110 SAN 110 SAN Controller verifies identity of Queue Manager
 115 If identity confirmed, SAN Controller confirms connection request, else refuses connection

Interaction 2 - Defining a Queue

200 Administrator 200 Administrator sends a request to define a queue on the SAN 205 SAN 205 SAN Controller validates and if appropriate, accepts request 210 SAN 210 SAN Controller allocates space for the queue on managed storage 215 SAN 215 SAN Controller builds necessary control structures 220 SAN 220 SAN Controller confirms completion of queue creation

30

5

10

15

Interaction 3 - Opening a handle to a queue 300 Queue 300 Queue Manager sends request to open a handle to a queue 305 SAN 305 SAN Controller confirms existence of queue and authority to open handle 310 If queue does not exist or incorrect authority, fail the request 315 SAN315 SAN Controller opens and returns handle to requesting queue manager 5 320 __SAN Controller updates a usage counter for the queue Interaction 4 - Placing a message on the queue 400 __Queue Manager sends a message to place on a queue 405 __SAN Controller verifies authority to place message on queue. 10 410 SAN Controller writes message data into allocated, managed storage 415 __SAN Controller checks if write is part of syncpoint 420 __If part of syncpoint, SAN Controller places lock on message, confirms to application 425 __If not in syncpoint, SAN Controller confirms message written to queue 15 Interaction 5 - Confirming syncpoint (simplified) (read and write write operations) 500 Queue Manager sends syncpoint confirmation to SAN Controller 20 505 __SAN Controller confirms queue operation (read or write) 510 _SAN Controller clears lock on message, and removes message from queue if read operation Interaction 6 - Backing out syncpoint (simplified) (read and write operations) 25 600 __Queue Manager sends syncpoint back out to SAN Controller 605 __SAN Controller confirms queue operation backed out (read or write) 610 SAN Controller clears lock on message, and removes message from queue if write operation.

Note that any syncpoint operations would typically be of the two phase commit type, but this level of detail is not needed in the present description. Between the SAN Controller and an attached queue manager, a full two phase commit may not be necessary.

5	
	Interaction 7 - Reading a message from a queue
	700Queue Manager sends a read request message to SAN Controller
	705SAN Controller checks if request is for specific message. If so, Interaction 8 -
	Reading a specific message
10	710SAN Controller determines next available message to be read
	715If not a browse, SAN Controller locks message, and checks if read is under
	syncpoint
	720SAN Controller sends message and marks syncpoint if needed
	725If read is not a browse and out of syncpoint, message is removed from managed
15	storage
	Interaction 8 - Reading a specific message from a queue
	800SAN Controller checks if message exists and is not locked by other queue
	manager
20	805If message is locked or does not exist, read request is rejected
	810If not a browse, SAN Controller locks message, and checks if read is under
	syncpoint
	815SAN Controller sends message and marks syncpoint if needed
	820If read is not a browse and out of syncpoint, message is removed from managed
25	storage
	Interaction 9 - Closing a handle to a queue
	900Queue Manager sends request to close queue handle
	1.2

	905SAN Controller verifies request and decrements usage counter
	910SAN Controller checks the usage counter for the queue
	912SAN Controller checks for any uncommitted syncpoints, and if found, rejects
	close handle request
5	915If usage count is 0, SAN Controller deletes queue handle
	920If usage count is not 0, SAN Controller rejects close request
	Interaction 10 - Deleting a queue
	1000 _Administrator sends request to delete queue
10	1005 _If request is a "force delete" then delete queue and free allocated managed storage
	1015 _SAN Controller verifies that no messages are locked under syncpoint
	1020 _SAN Controller verifies that no other queue managers have open handles 1025 If above tests are true, then delete queue and free allocated managed storage
	1030 _If any tests above are false, then reject close request.
15	
	Interaction 11 - Listing owned queues
	1100 _Queue manager or system management API sends request to list owned queues
	1105 _SAN Controller sends details
20	Interaction 12 - Amending queue definition
	1200 _Queue manager or system management API sends request to amend queue definition
	1205 _SAN Controller verifies request possible and executes changes.
25	Interaction 13 - Queue Manager Health Check
•	1300 _SAN Controller sends health check to each connected queue manager
	1305 _If no response from health check, SAN Controller disconnects failed queue
	manager

Interaction 14 - Disconnect failed Queue Manager

- 1400 _SAN Controller terminates each handle owned by the failed queue manager
- 1405 _SAN Controller checks for all uncommitted syncpoints, and backs them out
- 5 1410 _SAN Controller closes all open handles to queue
 - 1415 _SAN Controller closes connection handle to failed queue manager
 - 1420 _SAN Controller reports failure event

GB920020038GB1 16GB9-2002-0038-US1

ABSTRACT

Messages can have the property of being persistent or they can be non-persistent.

A persistent message must be logged and journaled by the queue manager before any subsequent processing can occur, and a non-persistent message is discarded in the event of a queue manager failure. The centralization of messaging supported by the use of the SAN and SAN controller is particularly suitable for the control of queues where persistent messages may be placed.

Advantages Over The Prior Art

10

15

20

25

5

By moving the storage of messages to a SAN, support infrastructure in the SAN may be used to supply all required data integrity and functionality to allow multiple queue managers to access the queue simultaneously for read and write operations. Other advantages include removal of messages, i.e. data, from the application server where instead of being accessible by one server, the messages are potentially accessible by any server which can connect to the SAN. An addition of locking and two phase commit primitives to the SAN controller allows multiple servers to connect to the SAN and to simultaneously access the messages on the queues for reads, writes, deletes, locks, and transactional operations, with the same level of data integrity that is offered by a single queue manager controlling multi-threaded access to a single queue. Another benefit is that it is possible to filter all messages inbound to a particular application to one queue maintained in the SAN. From there they can be distributed to any number of connected servers for subsequent processing by the application with complete transparency to the application. Finally, since all message data is centrally located, providing for backup and disaster recovery is simplified as all persistent data is located in one place, and base SAN services can be utilized to ensure that a secure copy is made.

Alternative Embodiments

GB920020038GB1 18GB9-2002-0038-US1

It will be appreciated that, although specific embodiments of the invention have been described herein for purposes of illustration, various modifications may be made without departing from the spirit and scope of the invention. In particular, a set of protocols may be provided for data integrity, transactionality, and other qualities of service between the various components. In such a case, data integrity, syncpoint coordination, *etc.* would be conducted and controlled by a middleware layer, which would supply the appropriate set of primitives to the SAN controller and to the applications and queue managers. Accordingly, the scope of protection of this invention is limited only by the following claims and their equivalents.

10

	Abstract of the Disclosure
	ASYNCHRONOUS MESSAGING IN STORAGE AREA NETWORK
4	—A computer system includes an asynchronous messaging and queuing messaging-and-queuing system; and a storage area network having a storage area network controller; and the controller in communication with the asynchronous messaging-and-queuing system. The storage area network controller includes control means to control a message queue on behalf of one or more queue managers, which may be heterogeneous.
	The storage area network controller may also include means for
•	controlling persistence of messages, transactional control means, such as a syncpoint
•	coordinator, and data integrity control means, such as a lock manager.
